Abstract—Wireless sensor networks operating in the license-free spectrum suffer from uncontrolled interference as those spectrum bands become increasingly crowded. The emerging cognitive radio sensor networks (CRSNs) provide a promising solution to address this challenge by enabling sensor nodes to opportunistically access licensed channels. However, since sensor nodes have to consume considerable energy to support CR functionalities, such as channel sensing and switching, the opportunistic channel accessing should be carefully devised for improving the energy efficiency in CRSN. To this end, we investigate the dynamic channel accessing problem to improve the energy efficiency for a clustered CRSN. Under the primary users' protection requirement, we study the resource allocation issues to maximize the energy efficiency of utilizing a licensed channel for intra-cluster and inter-cluster data transmission, respectively. Moreover, with the consideration of the energy consumption in channel sensing and switching, we further determine the condition when sensor nodes should sense and switch to a licensed channel for improving the energy efficiency, according to the packet loss rate of the license-free channel. In addition, two dynamic channel accessing schemes are proposed to identify the channel sensing and switching sequences for intra-cluster and inter-cluster data transmission, respectively. Extensive simulation results demonstrate that the proposed channel accessing schemes can significantly reduce the energy consumption in CRSNs.

Index Terms—Cognitive radio sensor network, dynamic channel access, clustering, energy efficiency.

I. INTRODUCTION

WIRELESS sensor network (WSN), as a promising event monitoring and data gathering technique, has been widely applied to various fields including environment monitoring, military surveillance and other industrial applications [1], [2]. A typical WSN consists of a large number of battery-powered sensor nodes to sense a specific area and periodically

send the sensing results to the sink. Since sensor nodes are energy-constrained and generally deployed in unattended environment, energy efficiency becomes a critical issue in WSNs. Meanwhile, as the rapid growth of wireless services make the license-free spectrum increasingly crowded, WSNs operating over the license-free spectrum suffer from heavy interference caused by other networks sharing the same spectrum. The uncontrollable interference may cause a high packet loss rate and lead to excessive energy consumption for data retransmission, which significantly deteriorates the energy efficiency of the network.

Cognitive Radio (CR) has emerged as a promising technology to improve the spectrum utilization by enabling opportunistic access to the licensed spectrum bands [3]. This technology can also be applied to WSNs, which leads to Cognitive Radio Sensor Networks (CRSNs) [4]. Sensor nodes in CRSNs can sense the availability of licensed channels and adjust the operation parameters to access the idle ones, when the condition of the licensed-free channel degrades. However, since the energy consumption for supporting the CR functionalities, e.g., channel sensing and switching, is considerable for battery-powered sensor nodes [5], [6], the opportunistic channel access should be carefully studied to improve the energy efficiency in CRSNs.

Existing works provide a comprehensive and in-depth investigation on optimizing the quality-of-service (QoS) performances for CRSNs, such as reducing the transmission delay [7]–[9] or increasing the network capacity [10], [11]. However, few of them have paid attention to improving the energy efficiency for CRSNs, with a delicate consideration of the energy consumption in channel sensing and switching. In order to enhance energy efficiency, the key issue is to determine when the energy consumption of transmitting a fixed amount of data can be reduced by sensing and accessing a licensed channel, compared with the energy consumption when only using the default license-free channel. It is very challenging since the decision depends on different factors, including the packet loss rate of the license-free channel, the probabilities for accessing licensed channels, as well as the protection for primary users (PUs). Moreover, due to the dynamic availability of licensed channels, when sensor nodes decide to sense and access a licensed channel, another challenge lies in identifying the best licensed channel to sense and access to optimize the energy efficiency for data transmission.

In this paper, we investigate the opportunistic channel accessing problem to improve energy efficiency in clustered CRSNs. Sensor nodes form a number of clusters and periodically transmit their sensed data to the sink via hierarchical routing. They

work on a license-free channel but are also able to access idle licensed channels when the packet loss rate over the license-free channel increases. To protect the PUs sufficiently, the channel available duration (CAD) is limited for each licensed channel when it is detected as idle. Then, we analyze the expected energy consumption to determine if sensor nodes can reduce their energy consumption by accessing a licensed channel, considering the energy consumption in channel sensing and switching. Furthermore, to tackle the opportunistic availability of licensed channels, two sequential channel sensing and accessing schemes with the resource allocation of an accessed channel are exploited for minimizing the energy consumption in both intra- and inter-cluster data transmission. Specifically, the contributions of this work are three-fold.

- (i) For both intra-cluster and inter-cluster data transmission, we determine the condition when sensor nodes should sense and switch to a licensed channel for potential energy consumption reduction.
- (ii) We propose a dynamic channel accessing scheme to reduce the energy consumption for intra-cluster data transmission, which identifies the sensing and accessing sequence of the licensed channels within each cluster.
- (iii) Based on the analysis of intra-cluster data transmission, a joint power allocation and channel accessing scheme is developed for inter-cluster data transmission, which can dynamically adjust the transmission power of cluster heads and determine the channel sensing and accessing sequence to reduce energy consumption.

The remainder of this paper is organized as follows. Section II overviews related works. The system model and problem statement are introduced in Section III. In Section IV, we provide a detailed analysis of energy consumption for channel sensing decision and propose a dynamic channel sensing and accessing scheme for intra-cluster data transmission. Section V presents a joint power allocation and channel accessing scheme for inter-cluster data transmission. Simulation results are provided in Section VI to evaluate the performance of the proposed schemes. Finally, Section VII concludes the paper and outlines the future work.

II. RELATED WORKS

With ever-increasing wireless services and QoS requirements, traditional WSNs operating over the license-free spectrum, are facing unprecedented challenges to guarantee network performance. As an emerging solution for the spectrum scarcity of WSNs, CRSN has been well studied to improve the network performances, in terms of delay and throughput.

Liang et al. [7] analyze the delay performance to support real-time traffic in CRSNs. They derive the average packet transmission delay for two types of channel switching mechanisms, namely periodic switching and triggered switching, under two kinds of real-time traffic, including periodic data traffic and Poisson traffic, respectively. Bicen et al. [8] provide several principles for delay-sensitive multimedia communication in CRSNs through extensive simulations. A greedy networking algorithm is proposed in [9] to enhance the end-to-end delay and network throughput for CRSNs, by leveraging

distributed source coding and broadcasting. Since the QoS performances of sensor networks can be significantly impacted by routing schemes, research efforts are also devoted in developing dynamic routing for CRSNs [10], [11]. Quang and Kim [10] propose a throughput-aware routing algorithm to improve network throughput and decrease end-to-end delay for a large-scale clustered CRSN based on ISA100.11a. In addition, opportunistic medium access (MAC) protocol design and performance analysis of existing MAC protocols for CRSNs are studied in [12], [13].

Most of the existing works can effectively improve the network performances for various WSNs applications, and also provide a foundation for spectrum management and resource allocation in CRSNs. However, as a sensor network composed of resource-limited and energy-constrained sensor nodes, CRSN is still facing an inherent challenge on energy efficiency, which attracts increasing attention to study the energy efficiency enhancement.

Han et al. [14] develop a channel management scheme for CRSNs, which can adaptively select the operation mode of the network in terms of channel sensing, channel switching, and data transmission/reception, for energy efficiency improvement according to the outcome of channel sensing. The optimal packet size is studied in [15] to maximize energy efficiency while maintaining acceptable interference level for PUs and achieving reliable event detection in CRSNs. The transmission power of sensor nodes can also be adjusted for improving the energy efficiency of data transmission. In [16], Chai et al. propose a power allocation algorithm for sensor nodes to achieve satisfactory performance in terms of energy efficiency, convergence speed and fairness in CRSNs. Meanwhile, since spectrum sensing accounts for a certain portion of energy consumption for CRSNs, energy efficient spectrum sensing schemes are also studied in CRSNs to improve the spectrum detection performance [17], [18]. Furthermore, motivated by the superior energy efficiency of clustered WSNs, spectrum-aware clustering strategies are investigated in [19], [20] to enhance energy efficiency and spectrum utilization for CRSNs.

However, a comprehensive study on energy efficient data gathering is particularly important for CRSNs, which should jointly consider the energy consumption in channel sensing and switching, channel detection probability and PU protection to determine channel sensing and switching decision.

III. SYSTEM MODEL

A. Network Model

Consider a cognitive radio sensor network, where a set of cognitive sensor nodes $\mathcal{N} = \{s_1, \dots, s_n\}$ are distributed to monitor the area of interest, as shown in Fig. 1. According to the application requirements, sensor nodes periodically sense the environment with different sampling rates and then report their sensed data to the sink node [21]. We divide the operation process of the network into a large number of data periods. A data period is composed of data sensing, data transmission, and sleeping durations, where sensor nodes sense the monitored area, transmit the sensed data to the sink node, and then sleep, respectively. Motivated by the benefits of hierarchical

Fig. 1. The architecture of CRSN.

data gathering, sensor nodes form a number of clusters, denoted by $\mathcal{L} = \{L_1, \dots, L_m\}$, to transmit the sensed data to the sink [22]. Denote the cluster head (CH) of L_i as H_i , and the set of cluster members (CMs) in L_i as $\mathcal{N}_i$.

The data transmission is further divided into two phases: intra-cluster data transmission and inter-cluster data transmission. In the intra-cluster data transmission, CMs directly transmit their sensed data to the cluster heads in a Time Division Multiple Access (TDMA) manner. During the inter-cluster data transmission, CHs aggregate the sensed data and directly send the aggregated intra-cluster data to the sink. The inter-cluster data transmission is also based on a TDMA manner, coordinated by the sink. The sensor network operates on a license-free channel C_0 for data transmission, which may occasionally suffer from uncontrolled interference causing a significant packet loss rate. Enabled by the cognitive radio technique, sensor nodes can sense the licensed channels and access the vacant ones, when the packet loss rate of C_0 is fairly high. There is only one radio within each sensor node for data communication, which means sensor nodes can only access one channel at a time. Moreover, similar to most existing works [13], [23], we assume that sensor nodes use a network-wide common control channel for control signaling and channel access coordination.

B. Cognitive Radio Model

Suppose that there are k different licensed data channels $\mathcal{C} = \{C_1, \dots, C_k\}$ with different bandwidths $\{B_1, \dots, B_k\}$ in the primary network. The PU's behavior is assumed to be stationary and ergodic over the k channels. The cognitive sensor nodes in the primary network are secondary users (SUs) that can opportunistically access the idle channels. A fixed common control channel is considered to be available to exchange the control information among the sensor nodes and the sink. We model the PU traffic as a stationary exponential ON/OFF random process [3]. The ON state indicates that channel is occupied by PUs and the OFF state implies that the channel is idle. Let V_x and L_x be the exponential random variables, describing the idle and occupancy durations of C_x with means v_x and l_x , respectively. Thus, for each channel C_x , the probability of channel being idle p_{off}^x and the probability of channel occupancy p_{on}^x are

$$\begin{cases} p_{off}^x = v_x / (v_x + l_x), & \mathcal{H}_{0,x} \\ p_{on}^x = l_x / (v_x + l_x), & \mathcal{H}_{1,x} \end{cases}, \quad (1)$$

where $\mathcal{H}_{0,x}$ and $\mathcal{H}_{1,x}$ represent the hypothesis that C_x is idle and occupied, respectively. Sensor nodes are assumed to sense channel by the energy detection-based spectrum sensing approach [23]. When s_j adopts energy detector to sense C_x , the detection probability $p_{d,x,j}$ (i.e., the probability of an occupied channel being determined to be occupied correctly) and the false alarm probability $p_{f,x,j}$ (i.e., the probability of an idle channel being determined as occupied) are defined as $p_{d,x,j} = Pr(D_x \geq \delta_x | \mathcal{H}_{1,x})$ and $p_{f,x,j} = Pr(D_x \geq \delta_x | \mathcal{H}_{0,x})$, where δ_x is the detection threshold and D_x is the test statistic for C_x . And the misdetection probability can be calculated as $p_{m,x,j} = Pr(D_x < \delta_x | \mathcal{H}_{1,x}) = 1 - p_{d,x,j}$.

According to the analysis of [24], the false alarm probability of s_j for C_x can be given by $p_{f,x,j} = Q\left(\left(\frac{\delta_x}{\sigma_x^2} - 1\right)\sqrt{\varphi f_s}\right)$, where σ_x^2 is the variance of the Gaussian noise; φ is the sensing duration; f_s is the sampling frequency and $Q(\cdot)$ is the complementary distribution function of the standard Gaussian. The detection probability of s_j for C_x is given by $p_{d,x,j} = Q\left(\left(\frac{\delta_x}{\sigma_x^2} - \bar{\gamma}_{x,j} - 1\right)\sqrt{\frac{\varphi f_s}{2\bar{\gamma}_{x,j} + 1}}\right)$, where $\bar{\gamma}_{x,j}$ is the average received signal-to-noise ratio (SNR) over channel C_x at s_j .

To enhance the accuracy of sensing results, sensor nodes collaboratively perform channel sensing. Specifically, sensor nodes in the same cluster send the individual sensing results to the cluster head to make a combined decision. The decision rules at the cluster head can include AND rule, OR rule, etc. When OR rule is adopted, PUs are considered to be present if at least one sensor claims the presence of PUs. Then, if we use a number of sensor nodes, e.g., a set of sensor nodes $\mathbf{y}$, to cooperatively sense a channel, the cooperative detection probability F_d^x and the cooperative false alarm probability F_f^x for channel C_x are

$$F_d^x = 1 - \prod_{N_j \in \mathbf{y}} (1 - p_{d,x,j}), \quad F_f^x = 1 - \prod_{N_j \in \mathbf{y}} (1 - p_{f,x,j}) \quad (2)$$

The cooperative misdetection probability F_m^x is defined as the probability that the presence of the PU is not detected, i.e., $F_m^x = 1 - F_d^x$. In order to guarantee the accuracy of spectrum sensing, channel sensing should satisfy a requirement that the probability of interfering with PUs should be below a predefined threshold F_I . In other words, there is a constraint on $\mathbf{y}$ such that

$$p_{on}^x \cdot F_m^x = p_{on}^x \cdot \prod_{N_j \in \mathbf{y}} (1 - p_{d,x,j}) \leq F_I. \quad (3)$$

Given the signal transmission power P_j of s_j , the noise power σ_x^2 over C_x , and the average channel gain $h_{j,i,x}^2$ of the link between j and its destination node i over C_x , the transmission rate $R_{j,i,x}$ from j to i can be given as [25]:

$$R_{j,i,x} = B_x \log \left(1 + h_{j,i,x}^2 \frac{P_j}{\sigma_x^2} \right). \quad (4)$$

We consider that data transmission over each licensed channel C_x is error-free with the available channel capacity in Eq. (4).

During the intra-cluster data transmission, the transmission power of each sensor node is fixed to avoid co-channel interference among neighboring clusters [7]. The inter-cluster data transmission is also performed in TDMA, but CHs can adjust their transmission power for inter-cluster transmission when accessing a licensed channel. However, we assume that CHs do not adjust their power when they transmit data over C_0 , to avoid potential interference to other applications operating on this license-free channel [26]. The determination of the transmission power over the default license-free channel can be referred to existing solutions [27], [28], which is out of the scope of this paper.

C. Energy Consumption Model

The energy consumption of sensor nodes mainly includes four parts: the energy consumption for spectrum sensing, spectrum switching, data transmission and reception. For each sensor node, we use e_s to denote the energy consumption for sensing a licensed channel, which is fixed and the same for different channels. Meanwhile, sensor nodes need to consume energy to configure the radio and switch to a new channel. Therefore, we use e_w to denote the energy consumption that a sensor node consumes for channel switching. For s_j , the data transmission energy consumption $E_{j,t}$ is based on the classic energy model [29], i.e., $E_{j,t} = (P_j + P_{j,c}) \cdot t_{j,x}$, where $t_{j,x}$ is the data transmission time, P_j is the transmission power and $P_{j,c}$ is the circuit power at s_j . Following a similar model in [30], $P_{j,c}$ can be calculated as $P_{j,c} = \alpha_j + (\frac{1}{\eta} - 1) \cdot P_j$, where α_j is a transmission-power-independent component that accounts for the power consumed by the circuit, and η is the power amplifier efficiency. Physically, η is determined by the drain efficiency of the RF power amplifier and the modulation scheme [29], [30]. Therefore, we have the energy consumption of data transmission at s_j is

$$E_{j,t} = \frac{1}{\eta} \cdot P_j \cdot t_{j,x} + \alpha_j \cdot t_{j,x} = \frac{1}{\eta} (P_j + \alpha_{c,j}) \cdot t_{j,x}, \quad (5)$$

where $\alpha_{c,j} = \eta \cdot \alpha_j$ is defined as the equivalent circuit power consumption for data transmission. The energy consumption for data receiving is related to the data that a sensor node receives [22]. If s_j receives l bits data, the energy consumption is $E_{j,r} = e_c \cdot l$, where e_c is the circuit power for data receiving.

D. Problem Statement

Fig. 2 shows the time flow of the CRSN to illustrate the temporal relationship of different actions. As shown in the figure, a data period consists of three phases, i.e., data sensing, data transmission and sleeping. At the beginning of each data period, s_j senses the monitored area and generates A_j sensed data to report to the sink. Once the sensed data is successfully transmitted to the next hop, it will turn into sleep mode for energy saving and wait for the next data period. Since data transmission is independent among different data periods, our objective

Fig. 2. The time flow of CRSN.

is to efficiently transmit $A = \sum_{s_j \in \mathcal{N}} A_j$ data to the sink within a data transmission period, by determining the channel sensing and accessing decision according to the channel condition of C_0 . As an indicator of the time-varying channel condition, the packet loss rate of C_0 is measured/estimated at the beginning of each transmission period, by the RSSI (Received Signal Strength Indicator) and SNR (Signal-to-Noise Ratio) during the communications of each pair CM-CH and CH-Sink [31], [32], and assumed to be stable in a data transmission period but may vary over different periods [31].

According to the network model, the data transmission consists of two phases: intra-cluster data transmission and inter-cluster data transmission. Therefore, we focus on reducing the energy consumption during the two phases, respectively. Fig. 2 also shows the time flow of the two phases, which also describes the objectives of this work. Specifically, we aim to address the following two issues.

(1) During the intra-cluster data transmission, each cluster L_i should determine whether to sense and access a licensed channel according to the packet loss rate of C_0 . When L_i decides to sense and access a license channel, the channel sensing and accessing sequence should be determined for L_i to minimize the energy consumption of intra-cluster data transmission in a probabilistic way.

(2) During the inter-cluster data transmission, the channel sensing and accessing decision should also be carefully determined for potential energy consumption reduction. Since CHs can adjust their transmission power when accessing a licensed channel, the transmission power control and dynamic channel accessing should be jointly considered to minimize the energy consumption of inter-cluster data transmission.

To ease the presentation, the key notations are listed in Table I.

IV. DYNAMIC CHANNEL ACCESSING FOR INTRA-CLUSTER DATA TRANSMISSION

In this section, we propose a dynamic channel access solution for intra-cluster data transmission to improve the energy efficiency, according to the temporally fluctuated packet loss rate over C_0 . Specifically, we adopt a four-step analysis to introduce the main ideas of the proposed solution: (1) We analyze the energy consumption $E_{1,0}(i)$ for intra-cluster data transmission over C_0 in a cluster L_i ; (2) We calculate the optimal energy

TABLE I
THE KEY NOTATIONS

Notation	Definition
$\mathcal{N}, \mathcal{L}$	Set of sensor nodes $\{s_1, s_2, \dots, s_n\}$, set of clusters $\{L_1, L_2, \dots, L_m\}$
$H_i, \mathcal{N}_i$	Cluster head of L_i , set of sensor nodes in L_i
$\mathcal{C}$	Set of licensed channels $\{C_1, C_2, \dots, C_k\}$
C_0	The default license-free channel
B_x	Bandwidth of channel C_x
e_s, e_w	Energy consumption for channel sensing and switching
$R_{j,i,x}$	Data transmission rate from s_j to H_i over C_x
$h_{j,i,x}^2, \sigma_x^2$	Average channel gain between s_j and H_i over C_x , average noise power over C_x
$\lambda_{j,i,0}$	Packet loss rate between s_j and H_i over C_0
y	A fixed number of sensor nodes chosen for cooperative channel sensing
P_j	Transmission power of s_j over C_0 during intra-cluster data transmission
A_j	s_j 's sensed data needed to be transmitted during the intra-cluster data transmission
$E_{1,0}(i)$	Energy consumption of L_i by performing intra-cluster data transmission over C_0
p_r	PU protection requirement
T_x	The determined maximum channel available time of C_x under the required p_r
$t_{j,x}$	Allocated transmission time of s_j over an accessed licensed channel C_x
$\frac{E_{1,x}(i)}{E_{1,x}(i)}$	Energy consumption and expected energy consumption of L_i by performing intra-cluster data transmission over C_x
A_i	Aggregated data of H_i needed to be transmitted during inter-cluster data transmission
$E_{2,x}, \bar{E}_{2,x}$	Energy consumption and expected energy consumption of inter-cluster data transmission over C_x
$E'_{2,x}$	Equivalent energy consumption for optimizing $E_{2,x}$
$P_{i,x}, t_{i,x}$	Allocated transmission power and time of H_i over C_x during inter-cluster data transmission

consumption $E_{1,x}(i)$ in a cluster L_i , if L_i accesses a licensed channel C_x for intra-cluster data transmission; (3) Since there are different idle probabilities for the licensed channels, we further calculate the expected energy consumption $\bar{E}_{1,x}(i)$ for the intra-cluster data transmission in L_i by accessing C_x , taking the energy consumption of channel sensing and switching into consideration. Only if the packet loss rate over C_0 increases to a value making $E_{1,0}(i) > \bar{E}_{1,x}(i)$, C_x has the potential to improve the energy efficiency of intra-cluster data transmission; (4) When there are multiple licensed channels in $\mathcal{C}$ can potentially improve the energy efficiency, we propose a sequential channel sensing and accessing strategy, where the licensed channel C_x with a larger $(E_{1,0}(i) - \bar{E}_{1,x}(i))$ has a higher priority to be sensed and accessed by L_i , to achieve the highest energy efficiency improvement. In the following, we will detail the main ideas and mathematical analysis of each step, respectively.

A. Energy Consumption Analysis of Intra-cluster Data Transmission

Since each cluster aims to opportunistically access a licensed channel for intra-cluster data transmission to reduce the energy

consumption of transmitting intra-cluster data over C_0 , the original energy consumption should be calculated first if a cluster L_i ($L_i \in \mathcal{L}$) gathers the intra-cluster data over C_0 . According to the system model, the packet loss rate over C_0 can be measured for each communication link at the beginning of each data period. Given the measured packet loss rate of C_0 , **Proposition 1** analyzes the energy consumption of the clusters.

Proposition 1: For any cluster L_i ($L_i \in \mathcal{L}$), if the data amount of a cluster member s_j ($s_j \in \mathcal{N}_i$) is A_j , and the packet loss rate between s_j and the cluster head H_i over C_0 is $\lambda_{j,i,0}$, the energy consumption for intra-cluster data transmission is

$$E_{1,0}(i) = \sum_{s_j \in \mathcal{N}_i} \frac{A_j \cdot ER_{1,j}}{(1 - \lambda_{j,i,0})}, \quad (6)$$

where $ER_{1,j} = \frac{\eta \cdot R_{j,i,0} \cdot e_c + P_j + \alpha_{c,j}}{\eta \cdot R_{j,i,0}}$ means the energy consumption rate of s_j for transmitting intra-cluster data, $R_{j,i,0} = B_0 \log \left(1 + h_{j,i,0}^2 P_j / \sigma_0^2 \right)$ and P_j is s_j 's transmission power.

Proof: For each $s_j \in \mathcal{N}_i$, it generates A_j data to transmit during a data transmission period. Since the packet loss rate of C_0 is $\lambda_{j,i,0}$, the expected number of transmission attempts for each packet is $1/(1 - \lambda_{j,i,0})$. Therefore, the expected transmitted data is $A_j/(1 - \lambda_{j,i,0})$. If the transmission power of s_j is P_j , the data transmission time is $\frac{A_j}{(1 - \lambda_{j,i,0})R_{j,i,0}}$. Therefore, for all the sensor nodes in L_i , the energy consumption for data transmission is

$$\begin{aligned} e_{1,t}(i) &= \sum_{s_j \in \mathcal{N}_i} \left[\frac{A_j \cdot (P_j + \alpha_{c,j})}{\eta \cdot (1 - \lambda_{j,i,0}) \cdot R_{j,i,0}} \right] \\ &= \sum_{s_j \in \mathcal{N}_i} \left[\frac{A_j \cdot (P_j + \alpha_{c,j})}{\eta(1 - \lambda_{j,i,0})B_0 \log \left(1 + h_{j,i,0}^2 P_j / \sigma_0^2 \right)} \right]. \end{aligned} \quad (7)$$

Additionally, the energy consumption for receiving the sensed data is

$$e_{1,r}(i) = \sum_{s_j \in \mathcal{N}_i} \left(A_j \cdot \frac{1}{1 - \lambda_{j,i,0}} \cdot e_c \right). \quad (8)$$

Therefore, the total energy consumption of intra-cluster data transmission over C_0 is $E_{1,0}(i) = e_{1,t}(i) + e_{1,r}(i)$, which can be transformed to Eq. (6). It completes the proof. ■

B. Optimized Transmission Time Allocation for Intra-cluster Data Transmission

According to Eq. (6), the energy consumption for intra-cluster data transmission in L_i grows sharply with the increasing packet loss rate of C_0 . If we aim to access licensed channel C_x to reduce the intra-cluster energy consumption in L_i , we should first address the problem: how to allocate the transmission time of CMs to minimize the energy consumption with the consideration of PU protection. In this section, we focus on

determining the optimized energy consumption if L_i accesses C_x for data transmission.

When L_i accesses to C_x , the channel available duration (CAD) of C_x , denoted by T_x , is limited to control the interference probability to PUs, due to the fact that PUs may return at any time point and cause an interference with a certain probability. We define p_r as the PU protection requirement, which means the interference probability to PU during T_x should be no larger than p_r . According to the cognitive radio model, the PU traffic is an independent and identically distributed ON/OFF process, with v_x as the mean idle time. Thus, if C_x is accessed for T_x , the interference probability of C_x is $1 - e^{-v_x \cdot T_x}$. Meanwhile, the probability that C_x is idle and detected as idle is $p_{off}^x \cdot (1 - F_f^x)$. Therefore, the interference probability during T_x is $p_{off}^x \cdot (1 - F_f^x) \cdot (1 - e^{-v_x \cdot T_x})$, and the PU protection requirement is $p_{off}^x \cdot (1 - F_f^x) \cdot (1 - e^{-v_x \cdot T_x}) \leq p_r$. Based on that, the maximum CAD of C_x is

$$T_x = -\frac{1}{v_x} \ln \left(1 - \frac{p_r}{p_{off}^x \cdot (1 - F_f^x)} \right). \quad (9)$$

If T_x is large enough to guarantee the complement of the intra-cluster data transmission in L_i , all the data of CMs in L_i can be transmitted over C_x . Otherwise, T_x should be carefully allocated to the CMs of L_i to minimize the energy consumption, since CMs have different amounts of sensed data and different transmission rates, both of which can directly impact the energy consumption of intra-cluster data transmission. In the following, we mathematically formulate the transmission time allocation problem as an optimization problem, which will be solved to minimize the energy consumption of intra-cluster data transmission.

For channel C_x and cluster L_i , let $t_{j,x}$ be the allocated transmission time of s_j ($s_j \in \mathcal{N}_i$) over C_x . Then, the energy consumption of s_j for data transmission over C_x is $e_{j,x} = \frac{1}{\eta} (P_j + \alpha_{c,j}) \cdot t_{j,x}$. The residual data of s_j , if any, will be transmitted over C_0 , with the amount of $A_j - R_{j,i,x} \cdot t_{j,x}$. The associated energy consumption for transmitting the residual data over C_0 is $e_{j,0} = \frac{(A_j - R_{j,i,x} \cdot t_{j,x}) \cdot ER_{1,j}}{1 - \lambda_{j,i,0}}$. Let $E_{1,x}(i)$ be the total energy consumption for intra-cluster data transmission in L_i by accessing C_x . Then, we have $E_{1,x}(i) = \sum_{s_j \in \mathcal{N}_i} (e_{j,x} + e_{j,0})$. There are also some constraints for the transmission time allocation of T_x . For each CM $s_j \in \mathcal{N}_i$, the successfully transmitted data of s_j during the allocated time $t_{j,x}$ should be no larger than the generated data, which means

$$R_{j,i,x} \cdot t_{j,x} \leq A_j, \quad \forall s_j \in \mathcal{N}_i. \quad (10)$$

Meanwhile, the allocated transmission time $t_{j,x}$ of s_j should be no less than 0 and the total allocated transmission time of L_i should be no larger than T_x . Thus, we have

$$\begin{cases} \sum_{s_j \in \mathcal{N}_i} t_{j,x} \leq T_x, \\ t_{j,x} \geq 0, \quad \forall s_j \in \mathcal{N}_i. \end{cases} \quad (11)$$

We aim to determine the time allocation vector $\mathbf{t}_x = \{t_1, \dots, t_{|\mathcal{N}_i|}\}$ to minimize the energy consumption of intra-cluster data transmission, which can be formulated as the following optimization problem:

$$\begin{aligned} (\text{TAP}) \quad & \underset{\mathbf{t}_x}{\text{minimize}} \quad E_{1,x}(i) = \sum_{s_j \in \mathcal{N}_i} (e_{j,x} + e_{j,0}) \\ & \text{s.t.} \quad (10) \text{ and } (11). \end{aligned}$$

It can be seen that (TAP) is a classic linear programming problem. The well-known Simplex method can be directly applied to solve this problem [33]. In the following, we use $\mathbf{t}_x^* = \{t_1^*, \dots, t_{|\mathcal{N}_i|}^*\}$ and $E_{1,x}^*(i)$ to denote the optimal time allocation and energy consumption for intra-cluster data transmission by accessing C_x , respectively.

C. Analysis of Channel Sensing and Switching Decision for Intra-cluster Data Transmission

In this section, we focus on determining the condition when sensor nodes should sense and switch to a licensed channel for intra-cluster data transmission. By solving (TAP), we can obtain the optimal energy consumption for transmitting intra-cluster data over C_x . However, due to the uncertain availability of C_x and the energy consumption for channel sensing and switching, we can only obtain the expected energy consumption of intra-cluster data transmission by accessing C_x , if considering these two factors. According to the cognitive radio model, once L_i decides to sense a licensed channel, a number of CMs $\mathbf{y}$ should be chosen to perform cooperative sensing to achieve better sensing performance. Here, $|\mathbf{y}|$ is a system parameter to meet the constraint of Eq. (3), and we assume $|\mathbf{y}| \leq \min_{C_i \in \mathcal{C}} |\mathcal{N}_i|$.

Recall that, reducing the energy consumption of intra-cluster data transmission is the primary objective for channel sensing and switching. To determine if the energy consumption can be improved by sensing and switching to a licensed channel, we first define the expected accessible channel that is expectedly profitable for a cluster to sense and access.

Definition 1: For cluster L_i , an expected accessible channel is a channel, by accessing which the expected energy consumption for intra-cluster data transmission can be reduced, taking account of the energy consumption for channel sensing and switching, as well as the idle detection probability of this channel by cooperative sensing.

According to the definition, the following proposition determines the expected accessible channels for a specific cluster.

Proposition 2: For channel C_x , given detection probability P_d^x and false alarm probability P_f^x , the expected energy consumption for intra-cluster data transmission in L_i by accessing C_x is

$$\overline{E_{1,x}}(i) = E_{1,0}(i) + Y_{j,i,x} F_s^x t_{j,x}^* + 2|\mathcal{N}_i| e_w F_s^x + |\mathbf{y}| e_s, \quad (12)$$

and C_x is an expected accessible channel for L_i , if we have

$$Y_{j,i,x} \cdot F_s^x \cdot t_{j,x}^* + 2|\mathcal{N}_i| \cdot e_w \cdot F_s^x + |\mathbf{y}| \cdot e_s < 0, \quad (13)$$

where $F_s^x = p_{off}^x \cdot (1 - F_f^x)$ and $Y_{j,i,x} = \sum_{s_j \in \mathcal{N}_i} \left(\frac{(P_j + \alpha_{c,j})(1 - \lambda_{j,i,0}) - \eta ER_{1,j} R_{j,i,x}}{(1 - \lambda_{j,i,0}) \cdot \eta} \right)$.

Proof: For channel C_x with available time T_x , if it is used for intra-cluster data transmission in L_i , the optimal time allocation solution can be determined as $t_x^* = \{t_1^*, \dots, t_{|N_i|}^*\}$ by solving (TAP). Then, the optimal energy consumption for intra-cluster data transmission is

$$E_{1,x}^*(i) = \sum_{s_j \in N_i} \left[\frac{(P_j + \alpha_{c,j}) t_{j,x}^*}{\eta} + \frac{(A_j - R_{j,i,x} t_{j,x}^*) E R_{1,j}}{1 - \lambda_{j,i,0}} \right]. \quad (14)$$

If we consider the energy consumption for channel sensing and switching, the total energy consumption for using C_x in intra-cluster data transmission is $E_{1,x}^*(i) + |y| \cdot e_s + 2|N_i| \cdot e_w$. Meanwhile, if L_i decides to sense C_x , the probability that C_x is detected as available is $F_s^x = p_{off}^x \cdot (1 - F_f^x)$, according to the cognitive radio model¹. It means that we have a probability F_s^x to use C_x and a probability $1 - F_s^x$ to stay in channel C_0 . Therefore, the expected energy consumption for sensing and switching to C_x for intra-cluster data transmission is

$$\begin{aligned} \overline{E}_{1,x}(i) &= F_s^x \cdot (E_{1,x}^*(i) + |y| \cdot e_s + 2|N_i| \cdot e_w) \\ &\quad + (1 - F_s^x) \cdot (E_{1,0}(i) + |y| \cdot e_s) \end{aligned} \quad (15)$$

Substituting $E_{1,0}(i)$ and $E_{1,x}^*(i)$ according to Eq. (6) and (14), respectively, then Eq. (12) can be proved. If C_x is an expected accessible channel for L_i , the expected energy consumption should be less than $E_{1,0}(i)$, i.e., $\overline{E}_{1,x}(i) < E_{1,0}(i)$. Substituting $E_{1,0}(i)$ and $\overline{E}_{1,x}(i)$ with Eq. (6) and (15), we can obtain Eq. (13). ■

Based on **Proposition 2**, we have the following corollary to determine the condition in which the cluster L_i should sense licensed channels for intra-cluster data transmission.

Corollary 1: If there exists such channel $C_x \in \mathcal{C}$ that is an expected accessible channel of L_i , L_i should sense new channels for intra-cluster data transmission.

Proof: According to **Definition 1** and **Proposition 2**, the expected energy consumption for intra-cluster data transmission can be reduced in L_i by sensing and switching to the channel C_x , if C_x is an expected accessible channel of L_i . Therefore, if there exists such channel $C_x \in \mathcal{C}$ that can meet the constraint of Eq. (13), L_i should sense this licensed channel for the potential energy efficiency improvement. ■

D. Dynamic Channel Accessing for Intra-cluster Data Transmission

In this section, we propose a sequential channel sensing and accessing scheme for the intra-cluster data transmission of each cluster.

With **Corollary 1**, each cluster L_i can decide whether it should sense a licensed channel for intra-cluster data transmission according to the packet loss rate of the default channel C_0 . However, if there exist a set of expected accessible channels $\mathcal{C}'$ ($\mathcal{C}' \in \mathcal{C}$) for L_i , the problem is which one is

¹When C_x is detected as idle by cooperative sensing, there is also a probability that C_x is not available at this time, which is $p_{on}^x \cdot F_m^x$. However, this probability is limited below F_l by Eq. (3), thus, we ignore it in the analysis of this work.

Fig. 3. Procedures of the dynamic channel sensing and accessing scheme.

the most profitable to sense and access for intra-cluster data transmission. **Proposition 2** indicates that the channel with the lowest expected energy consumption $\overline{E}_{1,x}(i)$ should be sensed first. However, $\overline{E}_{1,x}(i)$ is only an expected value and the availabilities of licensed channels are totally opportunistic, which means the expected accessible channels may be detected as unavailable through spectrum sensing. Therefore, we arrange the expected accessible channel set $C_x \in \mathcal{C}'$ according to the increasing order $\overline{E}_{1,x}(i)$, and L_i senses the channels of $\mathcal{C}'$ one by one according to the order until detecting a channel as idle. Then, L_i switches to this channel for intra-cluster data transmission. Specifically, we discuss the dynamic channel sensing and accessing for intra-cluster data transmission in L_i in the following situations.

- (i) If $\mathcal{C}' = \emptyset$, it means that there is no expected accessible channel for L_i . The cluster does not sense any licensed channel and uses C_0 for intra-cluster data transmission.
- (ii) If $\mathcal{C}' \neq \emptyset$ and all the channels of $\mathcal{C}'$ are sensed as unavailable, L_i transmits the intra-cluster data over C_0 .
- (iii) If $\mathcal{C}' \neq \emptyset$ and C_x ($C_x \in \mathcal{C}'$) is sensed as idle by L_i , L_i switches to C_x and transmits the intra-cluster data over C_x . If the intra-cluster data is not completed after T_x , the channel sensing and accessing decision should be performed again. For each CM $s_j \in N_i$, we denote the residual data of s_j as A'_j . Then, we use A'_j in **Propositions 1** and **2** to determine the set of expected accessible channels $\mathcal{C}'$, and repeat the channel sensing and accessing according the three situations until the intra-cluster data transmission is finished in L_i .

Based on the discussion above, Fig. 3 shows a flow chart to illustrate the procedures. **Algorithm 1** presents the main idea of the dynamic channel sensing and accessing scheme for intra-cluster data transmission.

V. JOINT POWER ALLOCATION AND CHANNEL ACCESSING FOR INTER-CLUSTER DATA TRANSMISSION

After intra-cluster data transmission, CHs aggregate the received data, and then send the aggregated data to the sink.

Algorithm 1. Dynamic Channel Sensing and Accessing for Intra-cluster Data Transmission

Input: For each s_j and C_x , the sampling rate sr_j , the expected transmission rate $R_{j,i,x}$, packet loss rate $\lambda_{j,i,x}$, available transmission duration T_x , and other parameters in cognitive model and energy consumption model.

Output: Channel sensing and accessing sequence for intra-cluster data transmission.

```

Based on the analysis of intra-cluster data transmission, in this section, we focus on the channel accessing problem to improve the energy efficiency of inter-cluster data transmission. Similar to the analytical way of intra-cluster data transmission, we perform a four-step analysis to introduce the dynamic channel access solution for inter-cluster data transmission to improve the energy efficiency. If we consider all the CHs and the sink as a cluster where CHs are CMs and the sink is the CH, the inter-cluster data transmission is similar to the intra-cluster data transmission. However, since there is no interference for TDMA-based inter-cluster transmission over licensed channels, CHs can adjust their transmission power to transmit their data to the sink when accessing to a licensed channel.

A. Analysis of Channel Sensing and Switching Decision for Inter-cluster Data Transmission

Following the analytical path of intra-cluster data transmission, we first obtain the energy consumption of inter-cluster data transmission over C_0 in the following proposition. According to our model, CHs do not adjust their power when they transmit over C_0 , to avoid potential interference to other applications transmitting over this license-free channel. Therefore, we have the following proposition.

Proposition 3: Given the data aggregation rate of H_i ($L_i \in \mathcal{L}$) as ψ_i , the packet loss rate $\lambda_{i,s,0}$ between a cluster head H_i and the sink over C_0 , the energy consumption for inter-cluster data transmission over C_0 is $E_{2,0} = \sum_{H_i \in \mathcal{L}} \frac{A_i \cdot ER_{2,i}}{(1 - \lambda_{i,s,0})}$,

where $ER_{2,i} = \frac{\eta \cdot R_{i,s,0} \cdot e_c + P_{i,0} + \alpha_{c,j}}{\eta \cdot R_{i,s,0}}$ means the energy consumption rate of H_i for transmitting inter-cluster data over C_0 , $A_i = \sum_{s_j \in \mathcal{N}_i} A_j \cdot \psi_i$, $R_{i,s,0} = B_0 \log \left(1 + h_{i,s,0}^2 P_{i,0} / \sigma_0^2 \right)$ and $P_{i,0}$ is the transmission power of H_i .

Proof: Similar to the proof of **Proposition 1**. ■

We then determine the minimized energy consumption of inter-cluster data transmission by accessing licensed channel C_x . Based on Eq. (9), we can calculate the CAD of C_x as T_x . Note that, besides T_x , the transmission power of CHs can also be adjusted for the inter-cluster data transmission. For each H_i , let $P_{i,x}$ and $t_{i,x}$ denote the allocated transmission power and transmission time over C_x , respectively. The energy consumption of data transmission over C_x is $e_{i,x} = \frac{1}{\eta} (P_{i,x} + \alpha_{c,i}) \cdot t_{i,x}$, and the energy consumption of transmitting the residual data over C_0 , if any, is $e_{0,x} = \left[A_i - B_x \log \left(1 + \frac{h_{i,s,x}^2 P_{i,x}}{\sigma_x^2} \right) t_{i,x} \right] \cdot ER_{2,i} \cdot \frac{1}{1 - \lambda_{i,s,0}}$. To minimize the energy consumption, we can jointly determine the transmission power vector $\mathbf{P}_x = \{P_{1,x}, \dots, P_{m,x}\}$ and transmission time vector $\mathbf{t}_x = \{t_{1,x}, \dots, t_{m,x}\}$ of the CHs, which can be formulated as the following optimization problem:

$$\begin{aligned}
 (\text{PTAP}) \quad & \underset{\mathbf{P}_x, \mathbf{t}_x}{\text{minimize}} \quad E_{2,x} = \sum_{H_i \in \mathcal{L}} (e_{i,x} + e_{i,0}) \\
 \text{s.t.} \quad & \begin{cases} B_x \cdot \log \left(1 + \frac{h_{i,s,x}^2 P_{i,x}}{\sigma_x^2} \right) \cdot t_{i,x} \leq A_i, & \forall H_i \in \mathcal{L}, \\ \sum_{H_i \in \mathcal{L}} t_{i,x} \leq T_x, \\ t_{i,x} \geq 0, & \forall H_i \in \mathcal{L}, \\ 0 \leq P_i \leq P_{\max}, & \forall H_i \in \mathcal{L}, \end{cases}
 \end{aligned}$$

where $P_{\max}$ is the maximum power of CHs.

Since $P_{i,x}$ and $t_{i,x}$ are two continuous decision variables for each $H_i \in \mathcal{L}$, (PTAP) can be proved as a biconvex optimization problem. The analysis for the solution of (PTAP) will be discussed in the following subsection. Let $E_{2,x}^*$ denote the optimal energy consumption, and $\mathbf{P}_x^* = \{P_{1,x}^*, \dots, P_{m,x}^*\}$ and $\mathbf{t}_x^* = \{t_{1,x}^*, \dots, t_{m,x}^*\}$ denote the optimal allocated transmission power and time, respectively. Then, we can calculate

the expected energy consumption by accessing C_x and determine the expected accessible channel for inter-cluster data transmission with the following proposition.

Proposition 4: For channel C_x , given the detection probability P_d^x and the false alarm probability P_f^x , the expected energy consumption of inter-cluster data transmission by accessing C_x is

$$\overline{E_{2,x}} = E_{2,0} + Y_{i,s,x} F_s^x t_{i,x}^* + 2m e_w F_s^x + |y| e_s, \quad (16)$$

and C_x is an expected accessible channel for inter-cluster data transmission, if we have

$$Y_{i,s,x} \cdot F_s^x \cdot t_{i,x}^* + 2 \cdot m \cdot e_w \cdot F_s^x + |y| \cdot e_s < 0, \quad (17)$$

where $F_s^x = P_{off}^x \cdot (1 - P_f^x)$ and $Y_{i,s,x} = \sum_{s_j \in \mathcal{N}_i} \left(\frac{(P_{i,x}^* + \alpha_{c,i})(1 - \lambda_{i,s,0}) - \eta \cdot E R_{2,j} R_{i,s,x}}{(1 - \lambda_{i,s,0}) \cdot \eta} \right)$.

Based on **Proposition 4**, the following corollary provides the condition when CHs should sense licensed channels for inter-cluster data transmission.

Corollary 2: If there exists such channel $C_x \in \mathcal{C}$ that can be an expected accessible channel for inter-cluster data transmission, CHs should sense licensed channels to transmit inter-cluster data to the sink.

The proof to **Proposition 4** and **Corollary 2** are omitted, since they are similar to the proof of **Proposition 2** and **Corollary 1**.

B. Joint Transmission Power and Time Allocation for Inter-cluster Data Transmission

In this subsection, we aim to solve the joint transmission power and time allocation problem (i.e., **(PTAP)**) for minimizing the energy consumption of inter-cluster data transmission.

We first expand the objective function of **(PTAP)** as

$$E_{2,x} = \sum_{H_i \in \mathcal{L}} \frac{A_i \cdot E R_{2,i}}{1 - \lambda_{i,s,0}} + \sum_{H_i \in \mathcal{L}} \frac{(P_{i,x} + \alpha_{c,i}) \cdot t_{i,x}}{\eta} - \sum_{H_i \in \mathcal{L}} \frac{B_x \log \left(1 + h_{i,s,x}^2 P_{i,x} / \sigma_x^2 \right) t_{i,x} E R_{2,i}}{1 - \lambda_{i,s,0}}. \quad (18)$$

Since $\sum_{H_i \in \mathcal{L}} \frac{A_i \cdot E R_{2,i}}{1 - \lambda_{i,s,0}}$ is independent with the decision variables, **(PTAP)** is equivalent to minimizing the residual two parts of $E_{2,x}$. Let $W_i \stackrel{\text{def}}{=} \frac{B_x \cdot E R_{2,i}}{1 - \lambda_{i,s,0}}$ and $E'_{2,x} \stackrel{\text{def}}{=} \sum_{H_i \in \mathcal{L}} \frac{(P_{i,x} + \alpha_{c,i}) \cdot t_{i,x}}{\eta} - \sum_{H_i \in \mathcal{L}} \left(W_i \log \left(1 + \frac{h_{i,s,x}^2 P_{i,x}}{\sigma_x^2} \right) t_{i,x} \right)$, the equivalent problem of **(PTAP)** can be given as follows,

$$\text{(PTAP-E) minimize } E'_{2,x}$$

s.t. the same constraints as **(PTAP)**

In the following, we focus on solving **(PTAP-E)** instead of **(PTAP)**. The main idea of solving the biconvex problem is

to decouple the joint optimization problem into two sequential sub-problems. It can be achieved by first determining the optimal transmission power for a given transmission time t_x from the feasible set of transmission time. Then, using the determined optimal P_x to derive the optimal t_x , which can be iteratively used to determine the optimal transmission power. With sufficient iteration, we can obtain the optimal energy consumption. The detailed proof of this decoupling approach is provided in [29], [34]. Taking advantage of this property, the solution of **(PTAP-E)** can be determined as follows.

1) *Sub-Problem 1 - Optimization of Transmission Power P_x^* Under Given t_x :* We first calculate the optimal power allocation vector P_x^* , when the allocated transmission time vector t is fixed with $t_{i,x} \geq 0$ and $\sum_{H_i \in \mathcal{L}} t_{i,x} \leq T_x$. **(PTAP-E)** is equivalent to

$$\text{(PTAP-E1) minimize } E'_{2,x}(P_x)$$

$$\text{s.t. } \begin{cases} B_x \cdot \log \left(1 + \frac{h_{i,s,x}^2 P_{i,x}}{\sigma_x^2} \right) \cdot t_{i,x} \leq A_i, & \forall H_i \in \mathcal{L}, \\ 0 \leq P_{i,x} \leq P_{max}, & \forall H_i \in \mathcal{L}. \end{cases}$$

Obviously, **(PTAP-E1)** is a convex optimization problem, due to the convex objective function and convex feasible sets. Note that, the first constraint of **(PTAP-E1)** can be rewritten as a linear constraint $P_{i,x} \leq \left(2^{\frac{A_i}{B_x t_{i,x}}} - 1 \right) \cdot \sigma_x^2 / h_{i,s,x}^2$, because both B_x and $t_{i,x}$ are no less than 0 and the logarithm function is monotonously increasing over the feasible set. Therefore, we have the following proposition.

Proposition 5: If the optimal solution to **(PTAP-E1)** exists, i.e., the feasible set of **(PTAP-E1)** is not empty, the optimal power allocation P_x^* is

$$P_{i,x}^* = \begin{cases} 0, & \text{if } P_{i,x} |_{\frac{\partial f}{\partial P_{i,x}}=0} \leq 0; \\ P_{i,x} |_{\frac{\partial f}{\partial P_{i,x}}=0}, & \text{if } 0 < P_{i,x} |_{\frac{\partial f}{\partial P_{i,x}}=0} \leq P_{i,x}^B; \\ P_{i,x}^B, & \text{otherwise.} \end{cases}, \quad (19)$$

where $P_{i,x}^B = \min \left\{ \left(2^{\frac{A_i}{B_x t_{i,x}}} - 1 \right) \cdot \sigma_x^2 / h_{i,s,x}^2, P_{max} \right\}$ and $P_{i,x} |_{\frac{\partial f}{\partial P_{i,x}}=0} = \frac{W_i \cdot \eta}{\ln 2} - \frac{\sigma_x^2}{h_{i,s,x}^2}$.

Proof: Due to the convexity of **(PTAP-E1)**, the locally optimal solution is the globally optimal solution. Let $f(P_{i,x}) \stackrel{\text{def}}{=} \frac{(P_{i,x} + \alpha_{c,i}) \cdot t_{i,x}}{\eta} - W_i \log \left(1 + \frac{h_{i,s,x}^2 P_{i,x}}{\sigma_x^2} \right) t_{i,x}$. Its first-order partial derivate is

$$\frac{\partial f}{\partial P_{i,x}} = \frac{t_{i,x}}{\eta} - \frac{W_i \cdot t_{i,x} \cdot h_{i,s,x}^2}{\ln 2 (\sigma_x^2 + h_{i,s,x}^2 \cdot P_{i,x})}. \quad (20)$$

Let $\frac{\partial f}{\partial P_{i,x}} = 0$, we have $P_{i,x} = \frac{W_i \cdot \eta}{\ln 2} - \frac{\sigma_x^2}{h_{i,s,x}^2}$. Here, we set $P_{i,x} |_{\frac{\partial f}{\partial P_{i,x}}=0} \stackrel{\text{def}}{=} \frac{W_i \cdot \eta}{\ln 2} - \frac{\sigma_x^2}{h_{i,s,x}^2}$. Since $\frac{\partial f}{\partial P_{i,x}}$ is monotonously

Fig. 4. Illustration of solving (PTAP-E).

increasing over the constraint set of $P_{i,x}$, $f(P_{i,x})$ decreases when $P_{i,x} \leq P_{i,x}^*$, $\frac{\partial f}{\partial P_{i,x}}=0$, and the situation reverses when $P_{i,x} \geq P_{i,x}^*$, $\frac{\partial f}{\partial P_{i,x}}=0$. $f(P_{i,x})$ would achieve the maximum value at $P_{i,x}^*$, $\frac{\partial f}{\partial P_{i,x}}=0$.

Meanwhile, according to the constraints of $P_{i,x}$, the feasible set of $P_{i,x}$ is $P_{i,x} \leq \left(2^{\frac{A_i}{B_x t_{i,x}}} - 1\right) \cdot \sigma_x^2 / h_{i,s,x}^2$ and $P_{i,x} \leq P_{max}$. Let $P_{i,x}^B \stackrel{def}{=} \min \left\{ \left(2^{\frac{A_i}{B_x t_{i,x}}} - 1\right) \cdot \sigma_x^2 / h_{i,s,x}^2, P_{max} \right\}$. Then, we have $P_{i,x}^* = 0$ if $P_{i,x} \leq 0$; and $P_{i,x}^* = P_{i,x}$ if $0 < P_{i,x} \leq P_{i,x}^B$; otherwise, $P_{i,x}^* = P_{i,x}^B$. It completes the proof. ■

2) *Sub-Problem 2 - Optimization of Transmission Time t_x^* Under Given P_x^** : Given any feasible transmission time vector t_x , **Proposition 5** presents the optimal transmission power vector in terms of t_x if such an optimal solution exists. In this sub-problem, we aim to determine the optimal t_x^* for given P_x . The sub-problem 2 can be described as follows.

$$\begin{aligned}
 & \text{(PTAP-E2) minimize}_{t_x} E'_{2,x}(t_x) \\
 & \text{s.t.} \quad \begin{cases} B_x \cdot \log \left(1 + \frac{h_{i,s,x}^2 P_{i,x}}{\sigma_x^2} \right) \cdot t_{i,x} \leq A_i, & \forall H_i \in \mathcal{L}, \\ \sum_{H_i \in \mathcal{L}} t_{i,x} \leq T_x, \\ t_{i,x} \geq 0, & \forall H_i \in \mathcal{L}. \end{cases}
 \end{aligned}$$

Since $P_{i,x}$ is a fixed parameter in this sub-problem, (PTAP-E2) becomes a linear programming problem, similar to (TAP) of Section IV-B. The Simplex algorithm can be applied to determine the optimal t_x^* and energy consumption [33].

Based on the analysis of the two sub-problems with (PTAP-E), we focus on (PTAP) using the Alternative Convex Search method, which is a special case of the Block-Relaxation Methods [34]. We illustrate the main idea of addressing this biconvex problem in Fig. 4, and summarize the detailed procedures of our solution in **Algorithm 2**.

C. Joint Power Allocation and Channel Accessing for Inter-cluster Data Transmission

In this subsection, we propose a joint power allocation and channel accessing scheme for inter-cluster data transmission. Similar to the analysis in Section IV-D, the channel sensing decision is made according to **Corollary 2**. Moreover, the channel sensing and accessing sequence should follow the ordered expected accessible channel set with an increasing order of

Algorithm 2. Alternative Convex Search based Algorithm for Solving (PTAP)

Input: The parameters of (PTAP), convergence requirement ω , and the maximum iteration number Λ .

Output: Determining the optimal P_x^* and t_x^* , as well as the optimal energy consumption $E_{2,x}^*$.

- 1: Choose an arbitrary start point $\{P_x(0), t_x(0)\}$ from the feasible set of P_x and t_x , and set $k = 0$, $E_{2,x}(0) = 0$;
- 2: **repeat**
- 3: For given $t_x(k)$, determine the optimal $P_x(k+1)$ according to Eq. (19);
- 4: For given $P_x(k+1)$, determine the optimal $t_x(k+1)$ and $E_{2,x}(k+1)$ by solving the linear programming (PTAP-E2);
- 5: $k = k + 1$;
- 6: **until** $E_{2,x}(k) - E_{2,x}(k-1) \leq \omega$ or $k \geq \Lambda$;
- 7: **return** $P_x(k)$, $t_x(k)$, and $E_{2,x}(k) + \sum_{H_i \in \mathcal{L}} \frac{A_i \cdot E R_{2,i}}{1 - \lambda_{i,s,0}}$;

$E_{2,x}$. For the three situations considered in Section IV-D, they can be addressed during the inter-cluster data transmission with the same logic flow. However, as the transmission power of sensor nodes can be adjusted for different accessed channels, the channel accessing scheme during inter-cluster data transmission is combined with the power allocation scheme. We summarize the main idea of our joint power allocation and channel accessing scheme in **Algorithm 3**.

VI. PERFORMANCE EVALUATION

We evaluate the performance of the proposed schemes by extensive simulations on OMNET++ [21], [22]. We setup a network consisting of 200 sensor nodes forming 10 clusters. Sensor nodes are randomly deployed in a circular area with the network radius of 250 m, and the sink is located at the center. There are 15 licensed channels in the primary network, which can be sensed and accessed by the CRSN. All the channels including the default working channel C_0 are modeled as Rayleigh fading channels. For each channel C_x ($C_x \in \mathcal{C} \cup \{C_0\}$), the noise spectral density is 10^{-14} W/Hz (i.e., $\sigma_x^2 = B_x \cdot 10^{-14}$ W), and the channel gain between s_i and s_j is set as $h_{i,j,x}^2 = \gamma \cdot d_{i,j}^{-\mu}$, where γ is an exponential random variable with mean value 1, and $d_{i,j}$ is the distance between s_i and s_j , and $\mu = 3$. Instead of setting the parameters of PU traffic on different licensed channels, we directly set the probability that PU is on as $p_{on}^x = 60\%$ and the channel available duration (CAD) as $T_x = N(100, 20)$ ms for each C_x , where $N(a, b)$ means the normal distribution with mean value a and variance b . The other parameters, if not specified in the simulation figures, are given in Table II. To demonstrate the energy efficiency improvement, we compare the proposed schemes with an existing work, named Zhang's method [35] which does not consider the energy consumption of channel sensing and switching in dynamic channel access control, in terms of the energy consumption of intra- and inter-cluster data transmission. To make a fair comparison, the reward of accessing an idle

Algorithm 3. Joint Power Allocation and Channel Accessing for Inter-cluster Data Transmission

Input: For each H_i , the aggregated data amount of H_i and the packet loss rate $\lambda_{i,s,0}$ over C_0 , and the parameters in cognitive model and energy consumption model.

Output: Transmission power for cluster heads, the channel sensing and accessing sequence for inter-cluster data transmission.

- 1: Calculate the energy consumption E_2 over C_0 according to **Proposition 3**;
- 2: **for all** $C_x \in \mathcal{C}$ **do**
- 3: Determine $E_{2,x}^*$ and $\overline{E_{2,x}}$ by solving (PTAP) and according to **Proposition 4**, respectively;
- 4: **end for**
- 5: Determine the expected accessible channel set $\mathcal{C}'$ according to **Proposition 4**, and reorder $\mathcal{C}'$ as $\overline{\mathcal{C}'}$ according to increasing order of $\overline{E_{2,x}}$;
- 6: $k = 1$;
- 7: **while** $k \leq |\overline{\mathcal{C}}'|$ **do**
- 8: Sense the k -th channel C_k of $\overline{\mathcal{C}}'$;
- 9: **if** C_k is idle **then**
- 10: Go to **step 17**;
- 11: **end if**
- 12: $k = k + 1$;
- 13: **end while**
- 14: **if** $|\overline{\mathcal{C}}'| == 0$ **or** $k > |\overline{\mathcal{C}}'|$ **then**
- 15: Transmit the residual inter-cluster data over the default channel C_0 ;
- 16: **else**
- 17: Transmit the inter-cluster data over the channel C_k , and allocate the transmission time $t_{i,x}^*$ and adjust the transmission power to $P_{i,x}^*$ for each $H_i \in \mathcal{L}$, according to **Algorithm 2**;
- 18: **if** The CAD of C_k is expired **and** the inter-cluster data transmission is not completed **then**
- 19: Go to **step 1**;
- 20: **end if**
- 21: **end if**

licensed channel in Zhang's method is defined as the reduced energy consumption by transmitting data over the licensed channel than transmitting over C_0 . Moreover, the number of accessed channel for the intra-cluster data transmission in each cluster and inter-cluster data transmission is set as one.

A. Intra-cluster Data Transmission

We evaluate the performance of the dynamic channel sensing and accessing scheme for intra-cluster data transmission in this subsection. Fig. 5 shows the energy consumption of intra-cluster data transmission by accessing a specific licensed channel. In our proposed scheme, the CAD of the accessed channel is allocated to CMs according to the optimal solution of (TAP). We compare our scheme to the average allocation scheme, in which the CAD of the accessed channel is equally allocated to the CMs with residual data. It can be seen that our scheme

TABLE II
PARAMETER SETTINGS

Parameter	Settings
CMs' power for intra-cluster data transmission P_j	20 mW
CHs' power $P_{i,0}$ for inter-cluster data transmission over C_0	40 mW
CHs' maximum adjustable power when accessing licensed channels P_{max}	200 mW
Power amplifier efficiency η [29]	0.9
Circuit power $\alpha_{c,j}$ [29]	5 mW
Energy consumption for data receiving e_c	5 nJ/bit
Per-node energy consumption for sensing a licensed channel e_s [5]	1.31×10^{-4} J
Per-node energy consumption for channel switching e_w [6]	10^{-5} J
Data amount of sensor node A_j	$N(5, 0.5)$ Kb
Aggregation rate at CHs ϕ	70%
Number of cooperative sensing nodes $ y $	3
Bandwidth of license-free channel C_0	1 MHz
Bandwidth of licensed channel C_x	$N(2, 0.5)$ MHz
False alarm probability F_f^x	5%

Fig. 5. Energy consumption comparison for intra-cluster data transmission by accessing a specific licensed channel.

can achieve lower energy consumption than that of the average allocation scheme, when the CAD of the accessed channel is no large than 60 ms. After the CAD becomes larger than 60 ms, the energy consumption of two schemes converge to the same value. The reason is that a large CAD can guarantee that all the intra-cluster data are transmitted over the licensed channel, which leads to a minimum and stable energy consumption.

Fig. 6 compares the energy consumption of intra-cluster data transmission under different packet loss rates over C_0 . In this figure, the proposed scheme corresponds to **Algorithm 1**. It can be seen that energy consumption increases sharply with the increasing packet loss rate of C_0 , if the cluster only uses C_0 for intra-cluster data transmission. Moreover, the proposed algorithm has lower energy consumption than Zhang's method [35] in both intra- and inter-cluster data transmission. Especially when the packet loss rate of C_0 is low, Zhang's method even produces a higher energy consumption than transmitting on C_0 , but the proposed algorithm chooses to keep working on C_0 to avoid the energy consumption in channel sensing and switching.

Fig. 6. Energy consumption comparison for intra-cluster data transmission under different packet loss rates.

Fig. 7. Convergence speed of ACS based algorithm for solving (PTAP).

B. Inter-cluster Data Transmission

In this subsection, we aim to evaluate the performance of the joint power allocation and channel accessing scheme in inter-cluster data transmission. Fig. 7 shows the convergence speed of the ACS based algorithm for solving (PTAP), i.e., **Algorithm 2**. It can be seen that the algorithm can converge (or find the optimal solution) within 6 iterations, which indicates the proposed algorithm is highly efficient and can be applied to resource-limited sensor networks. Fig. 8 compares the energy consumption for inter-cluster data transmission under the proposed joint transmission power and time allocation scheme and the average allocation scheme. In the average allocation scheme, the CAD of the accessed channel is equally allocated to the CHs with residual data and CHs use the maximum power to transmit their data when using the accessed channel. In our scheme, the transmission time and power are allocated to CHs according to the optimal solution of (PTAP). From Fig. 8, we can see that the average allocation scheme consumes much more energy than our proposed scheme under both scenarios of $P_{max} = 50$ mW and $P_{max} = 200$ mW. Meanwhile, our proposed scheme has lower energy consumption when it has a larger range of adjustable transmission power.

Fig. 9 shows the comparisons of the energy consumption of inter-cluster data transmission using different schemes, with respect to different packet loss rates over C_0 . Similar to the

Fig. 8. Energy consumption comparison for inter-cluster data transmission by accessing a specific licensed channel.

Fig. 9. Energy consumption comparison in inter-cluster data transmission under different packet loss rates.

comparison in Fig. 6, our proposed scheme can achieve lower energy consumption than the others when the packet loss rate of C_0 is larger than 7%. Before that point, the energy consumption of our proposed scheme is the same as that of only using C_0 but much lower than that of Zhang's method. It indicates that the inter-cluster data transmission should keep performing over C_0 when the packet loss rate of C_0 is lower than 7%, because in such cases, the energy consumption of channel sensing and accessing degrades the energy efficiency. Moreover, compared with the intra-cluster data transmission in Fig. 6, licensed channels are sensed and accessed at a lower packet loss rate over C_0 . Because the heavy data traffic in inter-cluster data transmission can make the channel sensing and accessing profitable for energy consumption reduction, even with a low packet loss rate over C_0 .

C. Impacts of System Parameters

Fig. 10 shows the total energy consumption comparison under different amount of data traffic. With the increasing data amount transmitted by sensor nodes, the total energy consumption increases sharply if the CRSN uses C_0 for data transmission, while it only increases linearly under our proposed schemes. Moreover, higher data traffic indicates better energy consumption improvement. Fig. 11 shows the total

Fig. 10. Total energy consumption comparison under different amount of data traffic.

Fig. 11. Total energy consumption comparison under different numbers of licensed channels.

Fig. 12. Total energy consumption comparison under different sensing performance.

energy consumption comparison under different numbers of licensed channels. It can be seen that the total energy consumption in our proposed schemes decreases with the increasing number of licensed channels. Fig. 12 shows the impacts of channel sensing accuracy on the performance of the proposed algorithms. It can be seen from the figure that the energy consumption of the proposed algorithms increases significantly with the increasing false alarm probability of channel sensing.

VII. CONCLUSION

In this paper, we have studied the dynamic channel accessing problem to improve the energy efficiency in clustered CRSNs. By considering the energy consumption in channel sensing and switching, we have determined the conditions of sensing and accessing licensed channels for potential energy consumption reduction. It can provide some insights for making channel switching decisions in CRSNs, from the perspective of energy efficiency. Moreover, two sequential channel sensing and accessing schemes have been proposed for intra- and inter-cluster data transmission, respectively, which form a comprehensive solution to control the dynamic channel access in clustered CRSNs for achieving optimal energy efficiency. Extensive simulation results demonstrate that the proposed schemes can significantly reduce the energy consumption of data transmission and outperform the existing work without considering the energy consumption of channel sensing and switching. For our future work, we will investigate rechargeable CRSNs, where stochastic harvested energy can be leveraged to support the cognitive radio techniques.
